1

## Key ideas

- model the throughput of TCP
- why?
  - analysis could give insight
  - can project into future networks
  - maybe this tells how to improve TCP
  - what traffic is NOT like TCP
  - “TCP friendliness”
    - what other transport protocols are *like* TCP so that they can co-exist nicely

7

## Context

[Mathis97a, eqn 3]

$$BW = \frac{MSS}{RTT} \frac{C}{\sqrt{p}} \quad C = \sqrt{3/2}$$

- Series of increasingly complete models of TCP steady state performance
  - Floyd, 1991
  - Mathis et al, 1997
  - new contribution: add timeouts
- Parallel line of research: modeling *short* connections:
  - Heidemann, Obrazcka, Touch 1997
  - Cardwell, Savage, Anderson 1998

10

## Basic Approach

- model TCP in *rounds*
  - consider congestion avoidance (ignore slow-start)
  - each round is a flight of packets until their ACKs
  - model window size  $W$
- model TDP: series of rounds followed by a drop and a *Triple-Dup-ACK*
- make assumptions where necessary
  - losses are i.i.d., but at end of round all pkts are lost
- solve for mean values using probability

11

## Basic Approach, pictorially

$$Y_i = \sum_{k=0}^{(X_i/b)-1} \left( \frac{W_i-1}{2} + k \right) b + \beta_i$$

$$A: E[A] = (E[X] + 1)E[r]$$

## Result for Triple-Dup-ACKs

conclusion for triple-dup-ACK steady state (in segments):

$$B(p) = \frac{1}{RTT} \sqrt{\frac{3}{2bp}} + o(1/\sqrt{p})$$

[Padhye98a, eqn 20]

compare to Mathis et al's earlier result (in bytes):

$$BW = \frac{MSS}{RTT} \frac{C}{\sqrt{p}} \quad C = \sqrt{3/2}$$

[Mathis97a, eqn 3]

## What About Timeouts?

add  $Z^{TO}$  to estimate timeouts

$$E[Z^{TO}] = \sum_{k=1}^{\infty} L_k P[R=k] = T_0 \frac{1+p+2p^2+4p^3+8p^4+16p^5+32p^6}{1-p}$$

## Modeling a Limited Window

- Define  $W_{\max}$  as the window limit
- What is performance if window limited?
  - data sent per round:  $W_{\max}$
  - rounds until TDP:  $E[X]$  (solved for previously)
  - so data sent in TDP =  $E[Y] = E[X] * W_{\max}$  (pkts per round)

## Back to $B(p)$

with timeouts: [Padhye98a, eqn 29]

$$B(p) \approx \frac{1}{RTT \sqrt{\frac{2bp}{3}} + T_0 \min \left( 1, 3 \sqrt{\frac{3bp}{8}} \right) p(1+32p^2)}$$

with timeouts and limited windows: [Padhye98a, eqn 32]

$$B(p) \approx \min \left( \frac{W_{\max}}{RTT}, \frac{1}{RTT \sqrt{\frac{2bp}{3}} + T_0 \min \left( 1, 3 \sqrt{\frac{3bp}{8}} \right) p(1+32p^2)} \right)$$

## Validation

- Ok, nice math, but does it really work?
- Validation approach:
  - set up bulk transfers
  - compare measured data vs. analysis with and without timeouts

## Validation

[Padhye98a, figs 7 & 9]

## Insights and Results

- Users of this stuff
  - TCP friendly work
  - analytic-augmented simulation
- insights into TCP
  - timeouts are very frequent
  - why? loss (due congestion)
    - when is fast retx likely to fail? when you have more than one loss over one RTT of data

## Other observations

- XXX
